QUALITY CONTROL PROCEDURES (Optional)

I INTRODUCTION

BD BBL™ CDC Anaerobe 5% Sheep Blood Agar with Kanamycin and Vancomycin (KV) is an enriched, selective culture medium for the isolation of obligately anaerobic gram-negative bacilli from clinical specimens.

II PERFORMANCE TEST PROCEDURE

1. Reduce all anaerobic agar plates overnight at room temperature in a BD GasPak™ EZ anaerobic system.

2. Preparation of inocula
   a. Prepare the obligate anaerobe test cultures by swabbing the growth from a 2- to 5-day CDC Anaerobe 5% Sheep Blood Agar plate into a tube containing 5 mL of reduced Enriched Thioglycollate Medium containing vitamin K₁ and hemin. Mix well and adjust to a turbidity comparable to a 0.5 McFarland standard.
   
   **NOTE:** Cultures must be handled quickly to avoid prolonged exposure to oxygen. Total exposure time should not exceed 20 min.
   b. Use 18- to 24-h broth cultures of the facultatively anaerobic organisms diluted 10⁻¹.

3. Inoculation of the plates
   a. Using a volumetric pipettor or equivalent method, deliver 0.05 mL of the appropriate inoculum to the plated media samples and streak for isolation. For Proteus mirabilis, use a 10⁻³ dilution of the broth culture as the inoculum.
   b. Include BD Trypticase™ Soy Agar with 5% Sheep Blood (TSA II) plates as controls for all organisms and CDC Anaerobe 5% Sheep Blood Agar plates as controls for the obligate anaerobes.
   c. Incubate the TSA II plate controls aerobically at 35 ± 2 °C and all other plates anaerobically (BD GasPak EZ anaerobic system) at 35 ± 2 °C.

4. Examine all inoculated plates at 48 h for amount of growth, colony size, pigmentation and hemolytic reactions. Observe the Porphyromonas and Prevotella strains under UV light (365 nm) for fluorescence up to 72 h (if necessary).

5. Expected Results

*Recommended organism strain for User Quality Control.

**Fluorescence is seen only in young colonies. Pigment develops slowly and may obscure fluorescence.

**NOTE:** This medium is exempt from User QC testing according to CLSI M22-A3. However, monitoring of exempt media used for anaerobes is strongly recommended.

III ADDITIONAL QUALITY CONTROL

1. Examine plates as described under “Product Deterioration.”
2. Visually examine representative plates to assure that any existing physical defects will not interfere with use.
3. Determine the pH potentiometrically at room temperature for adherence to the specification of 7.5 ± 0.2.
4. Note the firmness of plates during the inoculation procedure.
5. Incubate uninoculated representative plates at 35 ± 2 °C for 72 h and examine for microbial contamination.

PRODUCT INFORMATION

IV INTENDED USE

BD BBL™ CDC Anaerobe 5% Sheep Blood Agar with Kanamycin and Vancomycin is used for the selective isolation of fastidious and slow-growing, obligately anaerobic gram-negative bacteria from a variety of clinical and nonclinical materials.

V SUMMARY AND EXPLANATION

The isolation of obligately anaerobic bacteria from clinical and nonclinical materials requires the use of selective, nonselective and enrichment media.¹ The choice of media to be employed is based upon the type of material and the results of direct microscopic observation. Nonselective media are used to isolate organisms present in low numbers and to provide an indication of the numbers and types of organisms present in the specimen or sample. Selective media are employed to facilitate recovery of the desired organisms present in mixed populations.
BD BBL CDC Anaerobe 5% Sheep Blood Agar with Kanamycin and Vancomycin was formulated by Dowell et al. of the Centers for Disease Control and Prevention as an enriched, selective medium for the isolation of obligately anaerobic, gram-negative bacilli from clinical materials. The medium employs BD BBL™ Trypticase Soy Agar supplemented with additional agar, yeast extract, vitamin K₁, hemin, cystine, 5% sheep blood, kanamycin and vancomycin. The combination of kanamycin and vancomycin for use in selective isolation of gram-negative anaerobes was first described by Finegold et al. Vancomycin, however, may inhibit *Porphyromonas asaccharolytica.*

VI PRINCIPLES OF THE PROCEDURE
BD BBL CDC Anaerobe 5% Sheep Blood Agar with Kanamycin and Vancomycin is a highly nutritious medium due to its content of peptones, yeast extract, hemin, vitamin K₁ and sheep blood. The peptones provide nitrogenous growth factors, carbon, sulfur and trace ingredients. Yeast extract is an important source of B vitamins. Sodium chloride provides essential electrolytes. Sheep blood constituents, hemin, cystine and vitamin K₁ provide growth factors required by certain obligate anaerobes. The addition of the antimicrobial agents, kanamycin and vancomycin, renders the medium selective for gram-negative microorganisms. The kanamycin inhibits protein synthesis in susceptible organisms, whereas the vancomycin inhibits gram-positive bacteria by interfering with cell wall synthesis.

*Adjusted and/or supplemented as required to meet performance criteria.

Warnings and Precautions: For *in vitro* Diagnostic Use.

If excessive moisture is observed, invert the bottom over an off-set lid and allow to air dry in order to prevent formation of a seal between the top and bottom of the plate during incubation. Pathogenic microorganisms, including hepatitis viruses and Human Immunodeficiency Virus, may be present in clinical specimens. "Standard Precautions" and institutional guidelines should be followed in handling all items contaminated with blood and other body fluids. After use, prepare containers and other contaminated materials must be sterilized by autoclaving before discarding.

Storage Instructions: On receipt, store plates in the dark at 2–8 °C. Avoid freezing and overheating. Do not open until ready to use. Minimize exposure to light. Prepared plates stored in their original sleeve wrapping at 2–8 °C until just prior to use may be inoculated up to the expiration date and incubated for recommended incubation times. Allow the medium to warm to room temperature before inoculation.

Product Deterioration: Do not use plates if they show evidence of microbial contamination, discoloration, drying, cracking or other signs of deterioration.

VIII SPECIMEN COLLECTION AND HANDLING

Specimens suitable for culture may be handled using various techniques. For detailed information, consult appropriate texts. Specimens should be obtained before antimicrobial therapy has been administered. Provision must be made for prompt delivery to the laboratory.

IX PROCEDURE

Material Provided: BD BBL CDC Anaerobe 5% Sheep Blood Agar with Kanamycin and Vancomycin (KV)

Materials Required But Not Provided: Ancillary culture media, reagents, quality control organisms and laboratory equipment as required.

Test Procedure: Observe aseptic techniques.

The agar surface should be smooth and moist, but without excessive moisture.

Streak the specimen as soon as possible after it is received in the laboratory. Minimize exposure to air. With liquid specimens, media should be inoculated with 1 drop of the specimen. Tissue specimens should be minced and then ground in sterile broth such as BD BBL™ Trypticase Soy Broth. Inoculate the primary isolation plates.

Inoculation is then performed as for liquid specimens. Swab specimens may be rolled onto the first quadrant of plated media and then used to inoculate liquid media. Alternatively, the swab may be “scrubbed” in a small volume of reduced broth and the broth used to inoculate media as performed with liquid specimens.

This medium should be reduced immediately prior to inoculation by placing under anaerobic conditions for 6–24 h. An efficient and easy way to obtain suitable anaerobic conditions is through the use of BD GasPak EZ anaerobic systems.

Plated media should be inoculated using the streak plate method in order to obtain pure cultures from specimens containing mixed flora. An enrichment broth such as BD BBL™ Enriched Thiglycollate Broth should be inoculated at the same time as the primary isolation plates. Incubate immediately under anaerobic conditions or place in a holding jar flushed with oxygen free gas(es) until sufficient plates are accumulated (but no longer than 3 h). Incubation should be at 35 ± 2 °C for at least 48 h and up to 7 days. Regardless of anaerobic system used, it is important to include an indicator of anaerobiosis such as the BD GasPak disposable anaerobic indicator.

User Quality Control: See “Quality Control Procedures.”

Each lot of media has been tested using appropriate quality control organisms and this testing meets product specifications and CLSI standards, where relevant. As always, QC testing should be performed in accordance with applicable local, state, federal or country regulations, accreditation requirements, and/or your laboratory’s standard quality control procedures.
X RESULTS
After incubation, most plates will show an area of confluent growth. Because the streaking procedure is, in effect, a “dilution” technique, diminishing numbers of microorganisms are deposited on the streaked areas. Consequently, one or more of these areas should exhibit isolated colonies of the organisms contained in the specimen. Further, growth of each organism may be semiquantitatively scored on the basis of growth in each of the streaked areas.

Examine colonies using a dissecting microscope and with a long-wave UV lamp (colonies of the pigmenting Porphyromonas-Prevotella species should fluoresce orange to brick-red under UV light). Fluorescence is visible before pigmentation.

In order to determine the relationship to oxygen of each colony type present on anaerobic solid media, inoculate the following media:17
1. One anaerobe blood agar plate to be incubated anaerobically.
2. One aerobic blood agar (or chocolate agar) plate to be incubated in an aerobic atmosphere enriched with carbon dioxide. The chocolate agar is particularly needed to distinguish nutritionally-fastidious Haemophilus species and other bacteria which will grow on anaerobe blood agar incubated anaerobically and on chocolate agar under increased carbon dioxide tension but which fail to grow on blood agar in the presence of carbon dioxide or in air.
3. One aerobic blood agar plate to be incubated aerobically without added carbon dioxide.
4. Tubes of Enriched Thioglycollate Medium and/or Cooked Meat Medium and a tube of Peptone Yeast Extract Glucose Broth. Incubate all cultures at 35 ± 2 °C for a minimum of 24 h and up to 7 days.

Record the relationship to oxygen as either obligate anaerobe or nonanaerobe (aerotolerant anaerobe, microaerophilic, or facultative anaerobe).17

Organisms failing to grow on the aerobic subculture plates may be presumed to be obligately anaerobic in terms of their oxygen requirements. Colonies of the type(s) which prove to be obligate anaerobes can be further studied using the corresponding broth cultures.

XI LIMITATIONS OF THE PROCEDURE
The concentration of vancomycin (7.5 µg/mL) may be inhibitory to asaccharolytic Porphyromonas species.21,23
For identification, organisms must be in pure culture. Morphological, biochemical, and/or serological tests should be performed for final identification. Consult appropriate texts for detailed information and recommended procedures.8,15-25

A single medium is rarely adequate for detecting all organisms of potential significance in a specimen. It should be recognized that organisms generally susceptible to the antimicrobial agent in a selective medium may be completely or only partially inhibited depending upon the concentration of the agent, the characteristics of the microbial strain and the number of organisms in the inoculum. Organisms that are generally resistant to the antimicrobial agent should not be inhibited. Cultures of specimens grown on selective media should, therefore, be compared with specimens cultured on nonselective media to obtain additional information and help ensure recovery of potential pathogens.
